

Chapter 110

Fuel cell commercialization perspectives — market concepts, competing technologies and cost challenges for automotive and stationary applications

Timothy Lipman¹ and Daniel Sperling²

¹ Renewable and Appropriate Energy Lab (RAEL), University of California, Berkeley, CA, USA

² Institute of Transportation Studies, University of California, Davis, CA, USA

1 1 INTRODUCTION: THE HISTORY OF 2 FUEL CELL COMMERCIALIZATION

3
4
5 The concept of the fuel cell traces its roots all the way
6 back to William Grove's famous experiments on water
7 electrolysis in 1839, but the commercialization history of
8 fuel cell technologies remains rather limited over 150 years
9 later. Throughout the later part of the 19th and early
10 part of the 20th centuries, attempts were made to develop
11 fuel cells that could convert coal or some other carbon
12 material into electricity directly, but these attempts were
13 not successful because scientific knowledge of material
14 properties and electricity was lacking. The first fuel cell
15 capable of producing significant quantities of electricity was
16 developed by Francis Bacon in 1932. This system used
17 an alkaline electrolyte and nickel electrodes to produce
18 electricity using hydrogen and oxygen. By 1952, Bacon
19 had produced a 5 kW system, and this provided much of
20 the basis for further work on fuel cells in the 1950s and
21 1960s.

22 Fuel cell development received a boost in the late 1950s,
23 when the National Aeronautic and Space Administration
24 (NASA) determined that fuel cell technology was the most
25 promising option for producing electricity in space in a
26 compact and safe fashion. Nuclear power was consid-
27 ered too dangerous, batteries were too heavy, and solar

power was too cumbersome. NASA eventually funded over
200 research contracts for fuel cell technology, and used
both alkaline and proton-exchange membrane fuel cells
(PEMFCs) in the Apollo, Gemini, and space shuttle pro-
grams. The Gemini program utilized 1 kW PEMFC units
from 1965–66, while 1.5 kW alkaline fuel cell (AFC) units
were used in the Apollo program from 1968–1972. More
recently, three 12 kW AFC units have been used for at least
87 missions with 65 000 h flight time in the space shuttle
orbiter.^[1] All together more than 100 manned space flights
have been made by the US, totaling over 90 000 h of oper-
ating time, and all of these have used fuel cell systems
developed by the United Technologies Corporation (UTC)
of Windsor, CT.

The experience of UTC and its International Fuel Cells
(IFC) unit with fuel cells for the space program led to the
development of the first truly commercial fuel cell system,
the PC25 phosphoric acid fuel cell (PAFC) product. This
stationary fuel cell generating system, now in its third gen-
eration design, produces electricity from natural gas that is
reformed into a hydrogen-rich gas stream before being sup-
plied to the fuel cell stack. PC25s were first manufactured
by IFC's ONSI division in 1991, and approximately 200 of
these 200 kW fuel cell systems have now been purchased
and deployed throughout the US and in other countries.
Many of these systems were either procured under a US

2 Future prospects of fuel cell systems

55 Department of Defense (DOD) fuel cell purchase program,
56 where about 30 units were purchased and operated at US
57 DOD facilities, or through a \$1000 kW⁻¹ fuel cell purchase
58 subsidy program also administered through the US DOD.^[2]

59 For motor vehicle applications, General Motors has the
60 longest history among major automakers, having experi-
61 mented with fuel cell technology in the 1960s and having
62 demonstrated the world's first drivable fuel cell passen-
63 ger vehicle in 1966. General Motors designed this vehicle,
64 called the "Electrovan", with liquid hydrogen and oxygen
65 fuel tanks, and it achieved a range of 150 miles and a
66 top speed of 70 miles h⁻¹. The Electrovan program demon-
67 strated General Motors' early interest in developing fuel
68 cell vehicles for commercial use, but it also uncovered the
69 several obstacles that then became the focus of research
70 and development. These included the needs for improved
71 electronics, breakthroughs in electrochemistry, and new fuel
72 cell stack and system materials.^[3]

73 During the decade of the 1990s, fuel cells experienced
74 an intense phase of research and development that led to
75 the formation of many new companies and the establish-
76 ment of new divisions within established companies, and a
77 complex series of corporate mergers and re-organizations.
78 Many different companies are now planning to commer-
79 cialize several different fuel cell technologies for a wide
80 range of markets. These fuel cell technologies include the
81 PEMFC, AFC, and PAFC technologies mentioned above,
82 but also higher temperature solid-oxide fuel cell (SOFC)
83 and molten carbonate fuel cell (MCFC) types. A variation
84 of the PEMFC can also use methanol directly, without first
85 reforming it into hydrogen; it is known as a direct-methanol
86 fuel cell (DMFC). There also is an interesting class of
87 metal/air fuel cells that could also be considered "mechani-
88 cally recharged" batteries, and that may be attractive for
89 certain niche applications.

90 Fuel cells are currently being developed for the following
91 applications:

- 92 • power for portable electronic devices (5–50 W)
- 93 • power for remote telecommunications applications
94 (100 W–1 kW)
- 95 • power for construction and outdoor recreation uses
96 (1–3 kW)
- 97 • auxiliary power units for cars and trucks, and motive
98 power for scooters (3–5 kW)
- 99 • stationary power generation (1 kW–50 MW)
- 100 • electric passenger car, utility vehicle, and bus power
101 systems (20 kW–250 kW).

102
103 Some fuel cell companies are focusing on a single fuel
104 cell type and application combination, while other compa-
105 nies are investigating more than one fuel cell technology
106 and various potential applications. The following sections

of this chapter briefly describe the current state of fuel cell
industries for the stationary power and transportation mar-
kets, some of the commercialization plans for these two
sectors, and additional thoughts about prospects for mar-
ket commercialization of fuel cell technology. We do not
discuss in detail the prospects for fuel cell for portable elec-
tronic devices, since this application is rather distinct and
still at a relatively early stage of development.

2 CURRENT STATUS OF FUEL CELL TECHNOLOGY FOR STATIONARY APPLICATIONS

Fuel cells are under intense development for use as dis-
tributed generation (DG) resources. DG consists of small,
modular power systems that are sited at or near their point
of use. Typical DG systems are smaller than 30 MW and
may include such technologies as gas turbines, reciprocating
engines, biomass-based generators, concentrating solar
power and photovoltaic systems, wind turbines, micro-
turbines, and flywheel storage devices, in addition to fuel
cells. The advantages of DG compared with conventional
large-scale power plants include the ability to capture waste
heat to "cogenerate" heat as well as electrical power,
reductions in transmission losses, the ability to get around
transmission and distribution "bottlenecks" and to defer
substation upgrades, and the ability to achieve higher levels
of reliability.

In fact, the market for DG is to a significant extent
aimed at customers dependent on reliable energy, such as
hospitals, manufacturing plants, grocery stores, restaurants,
and banking facilities. DG owned by these customers can
provide peak-shaving, cogeneration, and stand-by power,
and these services translate into direct customer benefits.
Fuel cells can also be used in a stand-alone configuration
to supply power in remote locations where grid power
is not available. In addition to this customer-owned DG
model, however, utility-owned DG is another possibility
that can provide benefits to the utility when DG resources
are installed on the utility side of the meter. These benefits
include the ability to serve loads where transmission and
distribution are constrained, and the ability to provide
voltage support and other grid ancillary services from the
DG facilities.

Fuel cell technologies being developed for use in station-
ary DG applications include PEMFCs, PAFCs, SOFCs, and
MCFCs. In general, PEMFCs, PAFCs, and SOFCs are being
developed for smaller DG applications in the 1–300 kW
scale. These systems would serve the loads of individual
buildings, or perhaps small groups of adjacent buildings.
For larger scale applications, in the range of 300 kW–3 MW

159 or more, SOFC and MCFC systems are being developed,
 160 with particular focus on MCFC for MW scale applications.
 161 Stationary fuel cell systems are generally expected to run
 162 on pipeline natural gas that is either externally or internally
 163 reformed into hydrogen before being reacted in the fuel
 164 cell stack. In the external reforming process, a special fuel
 165 reformer is included as part of the system and this fuel
 166 reformer uses one of several possible methods to remove
 167 the hydrogen from the carbon "backbone" of the methane
 168 molecule. Reformer types include steam-methane reform-
 169 ers, partial oxidation reformers, and auto-thermal reformers,
 170 all of which differ with regard to the chemical processes
 171 used, efficiencies and capital costs. Steam methane reform-
 172 ing is the most mature of these technologies, having been
 173 used for commercial hydrogen production for many years,
 174 but other reformer technologies are also being developed.
 175 Internal reforming occurs in the higher temperature SOFC
 176 and MCFC types, and is the process whereby methane is
 177 reformed directly into a $H_2/CO/CO_2$ gas mixture due to the
 178 high temperatures. These fuel cell types thus do not need
 179 the complicated external reformer, and this is an advantage
 180 from a capital cost and system complexity perspective.

181 In addition to pipeline natural gas, stationary fuel cells
 182 could also operate on anaerobic digester gas, which con-
 183 tains methane in a mixture with carbon dioxide, oxygen, and
 184 nitrogen, or landfill gas that is produced naturally at land-
 185 fills. They could also operate on any other fuel that can be
 186 readily reformed into hydrogen, including propane, butane,
 187 methanol, ethanol, kerosene, dimethyl ether and naphtha,
 188 among others.

189 A significant barrier to the use of fuel cells as station-
 190 ary DG resources has been the high capital costs of the
 191 fuel cell systems that have been sold or demonstrated thus
 192 far. The IFC PC-25 200 kW PAFC units have sold for
 193 approximately \$4000 per kW, not including installation
 194 costs. Fuel cell energy has quoted costs of \$5000 kW⁻¹
 195 for its MCFC field trial units, with selling prices of about
 196 \$3000 kW⁻¹ expected when its manufacturing capability
 197 reaches 50 MW year⁻¹ in late 2001 or 2002. These high
 198 capital costs restrict the cost-effective application of fuel
 199 cell technology for stationary applications to locations
 200 where grid power is either unavailable or where extending
 201 distribution lines is expensive or infeasible. As fuel cell
 202 system costs decline, however, new markets will become
 203 accessible. These market opportunities are discussed below.

205 3 CURRENT STATUS OF FUEL CELL 206 TECHNOLOGY FOR 207 208 TRANSPORTATION APPLICATIONS

209 There has been a strong push to develop fuel cells for use
 210 in light-duty and heavy-duty vehicle propulsion since about

211 the early 1990s. Most attention is focusing on the use of
 212 PEMFCs for transportation applications, with the fuel cell
 213 systems running on either pure hydrogen or reformat from
 214 refinery products or methanol. This focus on PEMFC is
 215 mainly due to their low temperature operation and their
 216 capability for intermittent operation, but efforts are also
 217 underway to develop DMFCs and AFCs for vehicle appli-
 218 cations, as well as SOFC auxiliary power units (APUs).

219 Great strides have been made in increasing the power
 220 density of PEMFC systems, and this has significantly
 221 improved the practicality of using PEMFCs as the primary
 222 power source for fuel cell electric vehicles (FCVs). The
 223 progress of two of the leading companies in developing
 224 PEMFCs for vehicles, Ballard Power Systems and Gen-
 225 eral Motors, demonstrates the great achievements that have
 226 been made. In 1989, Ballard's PEMFC stacks achieved just
 227 100 W l⁻¹ of power density. By 1996, just 7 years later,
 228 over 1100 W l⁻¹ were achieved, representing greater than
 229 an order of magnitude improvement.^[4] Ballard's current
 230 PEMFC stack technology for transportation applications,
 231 the Ballard Mark 900 series of fuel cells, is designed
 232 for high-volume manufacturing. The Mark 902, unveiled
 233 in late 2001, achieves a remarkable 2200 W l⁻¹ of power
 234 density.^[5]

235 Similarly, General Motors has recently unveiled two new
 236 generations of PEMFC stack technology that show remark-
 237 able progress. First, the "Stack 2000" is a 200 cell design
 238 that has been incorporated into General Motors' HydroGen I
 239 and Chevy S-10 FCV prototypes, and has demonstrated a
 240 power density of 1600 W l⁻¹ in a 94 kW (continuous) fuel
 241 cell stack.^[6] In the Chevy S-10 pickup truck prototype, the
 242 Stack 2000 is coupled with General Motors' Gen II gaso-
 243 line fuel processor, that converts "clean" gasoline into a
 244 hydrogen rich gas stream for the fuel cell system (Gen-
 245 eral Motors, 2001). Second, General Motors has recently
 246 announced an even more advanced stack design that is
 247 reported to pack 1750 W l⁻¹ into a 640 cell design that
 248 is rated at 102 kW continuous and 173 kW peak.^[7]

249 A cutaway drawing of the prototype DaimlerChrysler
 250 NECAR 4 that employs PEMFC technology from Ballard,
 251 shown in Figure 1,^[8] illustrates how modern fuel cell sys-
 252 tems can now be packaged into small light-duty vehicles.
 253 This Mercedes A-Class vehicle uses a liquid hydrogen stor-
 254 age tank and a 55 kW electric drivetrain. Another NECAR
 255 4 design uses a compressed gas hydrogen tank, and the
 256 NECAR 5 design runs on methanol that is reformed into
 257 hydrogen onboard the vehicle.

258 However, despite these great improvements in auto-
 259 motive PEM fuel cell system power density, significant
 260 challenges remain for the commercialization of FCVs.
 261 Two recent studies have helped to identify the remaining
 262 challenges.^[9, 10] These challenges include:

4 Future prospects of fuel cell systems

Figure 1. The DaimlerChrysler NECAR 4 DHFCV. (Figure from DaimlerChrysler AG; DaimlerChrysler, Corporate Communications, Stuttgart (Germany), Auburn Hills, (MI/USA), 03/99.)

- 263 • the difficulty and expense of developing a hydrogen
- 264 refueling infrastructure for direct-hydrogen FCVs
- 265 • the development of compact and low cost fuel reformers
- 266 for liquid hydrocarbon fueled FCVs
- 267 • the need for onboard storage systems for hydrogen that
- 268 are simultaneously safe, compact, lightweight, inexpensive,
- 269 and quick to refuel
- 270 • cost reductions in fuel cell stacks, auxiliaries, electric
- 271 motors, inverters, and peak-power batteries or ultracapacitors
- 272 and
- 273 • lack of strong market drivers and transportation energy
- 274 policies for FCVs.

275 These remaining difficulties for FCV commercialization
 276 are significant, but considerable efforts are being made to
 277 address them by automakers, energy companies, govern-
 278 ment research labs and agencies, and academic institutions.
 279 We believe that the chances are good that the efforts being
 280 made to bring FCVs to market will ultimately be success-
 281 ful, but these remaining challenges make the timing of the
 282 introduction of mass-market FCVs uncertain at this time.
 283

In addition to light-duty passenger vehicles, other trans-
 284 portation applications of fuel cell technology that are being
 285 explored include urban buses, heavy-duty truck APUs,
 286 delivery vehicles, fork lifts, airport baggage handling vehi-
 287 cles, mining vehicles, golf carts, scooters, boats, and even
 288 airplanes. Of these, the urban bus market segment has
 289 received the most attention, with fuel cell bus demonstration
 290 projects being conducted by Ballard Power Systems and
 291 the US Department of Energy (DOE) in conjunction with
 292 Georgetown University. Two generations of buses have
 293 been built at Georgetown, with the first one using an IFC
 294 PAFC system and the second using an Xcellsis PEMFC
 295 system, and both employing hybrid-electric drivetrains. A
 296 third generation bus is planned that will use a nonhybridized
 297 PEMFC system. Ballard/Xcellsis PEMFC "Zebus" buses
 298 have successfully operated in Vancouver, Chicago, and
 299 Sacramento, with the first trials starting in 1998, and Daim-
 300 lerChrysler has produced the earlier NEBUS and recent
 301 Citaro fuel cell bus that also employ Ballard fuel cells. The
 302 NEBUS and the Citaro are both fueled by eight compressed
 303 hydrogen tanks.
 304

305 hydrogen gas tanks that are carried on the roof over the
306 front axle. However, the 250 kW fuel cell system, which
307 in the NEBUS was in the back where the diesel engine is
308 typically located in conventional buses, is on the roof in
309 the center of the Citaro. Commercialization plans for the
310 Citaro and Zebus fuel cell buses are discussed below.

311 One interesting consideration for fuel cell systems devel-
312 oped for transportation applications is the possibility of
313 "hybridizing" the fuel cell system with batteries or other
314 energy storage system to provide a given amount of power
315 with a smaller fuel cell stack. The use of batteries or
316 capacitors would enable the recapture of braking energy
317 through regenerative braking, and it could lead to a more
318 cost-effective design (particularly in the near term) due to
319 high fuel cell stack costs, but it would also involve addi-
320 tional system complexity. Furthermore, for reformer-based
321 vehicles, hybridization of the fuel cell power system with
322 batteries is one approach to alleviating the problem of slow
323 reformer transient response. Of the recent fuel cell con-
324 cept vehicles, DaimlerChrysler's NECAR line and the Ford
325 P2000 are not hybridized, while Toyota's two vehicles, the
326 DaimlerChrysler Natrium, the Renault/Volvo vehicle, the
327 fuel cell version of the GM EV1, Nissan's prototype, and
328 VW's prototype all use batteries, and the Honda FCX-V3
329 and Mazda's vehicle use ultracapacitors.

330

331

332 4 UNIQUE ATTRIBUTES OF FUEL CELL 333 VEHICLES 334

335 Fuel cell vehicles have a somewhat unique set of require-
336 ments of fuel cell technology. First, automotive fuel cell
337 systems must be more lightweight and compact (i.e., have
338 high power densities by both mass and volume) than fuel
339 cell systems used for stationary applications (from about
340 20–250 kW). Second, they must be tolerant to rapid cycling
341 and on-road vibration, yet they must only operate reliably
342 for 5000 h or so, while stationary systems must be able to
343 operate for 40 000–50 000 h between major system over-
344 hauls. Third, fuel cell systems for vehicles must be able
345 to respond rapidly to transient demands for power, unless
346 they are "load-leveled" by hybridizing them with a battery
347 or ultracapacitor power systems. Fuel cells for stationary
348 systems may also be used for load-following with transi-
349 ent demand requirements, possibly with the aid of a peak
350 power battery system, but they also will be used for steady
351 baseload power or "net metered" to allow constant power
352 operation if connected to the utility grid.

353 Given these requirements, hybrid and nonhybrid PEMFC
354 systems are the leading contenders for automotive fuel cell
355 power, with additional attention focusing on the DMFC
356 version of the technology and the possibility of using

SOFC systems as APUs for cars and trucks. All of these
fuel cell systems, both as main vehicle power systems
and as APUs have the ability to support the new wave
of vehicle electronics that is being introduced. New or
planned electronic gadgetry on vehicles include naviga-
tion systems, extensive onboard communications, voice-
actuated controls, exterior alternating current (a.c.) power
supplies, computer controlled power-assisted active suspen-
sion, collision-avoidance systems, electric A/C compres-
sors, "drive-by-wire" steering, side and rear-view bumper
cameras, electronic tire pressure control, and generally
greater computer power for increasing control of various
vehicle systems. The need for these systems has already
led to a new 42 V standard for vehicle auxiliaries in
order to deliver more power, and electric vehicles and APUs
provide an efficient way to meet these power demands.

More generally, FCVs are considered attractive poten-
tial replacements for internal combustion engine vehicles
because they can offer similar performance to conventional
vehicles along with several advantages. These advantages
include better environmental performance, quiet (but not
silent) operation, rapid acceleration from a standstill due
to the torque characteristics of electric motors, and poten-
tially low maintenance requirements. Furthermore, FCVs
have the potential to perform functions for which conven-
tional vehicles are poorly suited, such as providing remote
electrical power (for construction sites, recreational uses,
etc.) and possibly even acting as distributed electricity gen-
erators when parked at homes and offices and connected
to a supplemental fuel supply. Figure 2 presents the results
of one analysis of the full fuel-cycle air pollutant emis-
sions of hydrogen FCVs compared with conventional and
hybrid vehicles, and shows that FCVs running directly on
hydrogen can provide great potential air quality benefits.

One important feature of FCVs that remains crucial for
their development is the fact that PEM fuel cells run on

Figure 2. Fuel-cycle air pollutant impacts of hydrogen FCVs and gasoline powered alternatives. Source: ¹⁹¹ Notes: FC, fuel cell; HEV, hybrid electric vehicle; NMOG, nonmethane organic gases; NO_x, oxides of nitrogen; MY, model year; PZEV, partial zero-emission vehicle credit vehicle.

6 Future prospects of fuel cell systems

409 either pure hydrogen or a dilute hydrogen gas "reformat" 461
 410 stream (ignoring for a moment the prospects for direct- 462
 411 methanol fuel cells that are still in an early stage of 463
 412 development). This hydrogen can either be stored onboard 464
 413 the vehicle in one of several ways, or it can be gener- 465
 414 ated from another fuel with an onboard reformer. Onboard 466
 415 reformation introduces significant cost and complexity to 467
 416 FCVs, and also tends to diminish their energy efficiency and 468
 417 environmental benefits. For these reasons, most automak- 469
 418 ers agree that storing hydrogen onboard FCVs is the best 470
 419 ultimate solution, but no hydrogen storage system has yet 471
 420 been developed that is simultaneously lightweight, com- 472
 421 pact, inexpensive, and safe. Further advances in hydrogen 473
 422 storage, so that FCVs can refuel quickly and have driving 474
 423 ranges comparable to conventional vehicles, is thus a key 475
 424 area for further development. Prototype FCVs have been 476
 425 built that store hydrogen as a cryogenic liquid, as a com- 477
 426 pressed gas, in metal hydrides, and as sodium borohydrate, 478
 427 and other vehicles have been demonstrated with reformers 479
 428 for methanol and reformulated gasoline. 480
 429
 430

431 5 INNOVATION AND MARKETING 432 OF NEW PRODUCTS 433

434 Fuel cells, like all nascent technologies, are characterized by 486
 435 high manufacturing costs, uncertain long-term performance 487
 436 and durability, and lack of a clear technological consensus 488
 437 or "dominant design" for the individual niches for which 489
 438 they are being considered. As commercialization of fuel cell 490
 439 technology proceeds, manufacturing volumes will increase, 491
 440 costs will fall, and long-term product performance and dura- 492
 441 bility will be better understood. However, fuel cell systems 493
 442 will not easily or "automatically" penetrate stationary and 494
 443 automotive power markets, despite their attractive qualities. 495
 444 This is due not only to uncertain durability of fuel cells 496
 445 and potential cost differences between fuel cell systems 497
 446 and competing systems, but also because the incumbent 498
 447 technologies are typically "locked in" and have a series of 499
 448 network relationships that reinforce their continued use.^[11] 500
 449 For example, fuel cells for stationary applications fit into 501
 450 the emerging field of distributed generation (DG), but all 502
 451 DG technologies face difficulties in fitting into established 503
 452 electrical power systems that have been designed around 504
 453 large-scale centralized power production and a complex 505
 454 network of electricity transmission and distribution infras- 506
 455 tructure. Many regulatory and technical steps are needed 507
 456 for fuel cells and other DG technologies to safely intercon- 508
 457 nect to utility grids, and each of these represents a potential 509
 458 obstacle, particularly in the context of electricity industry 510
 459 restructuring and the uncertainty that this imposes on the 511
 460 industry. 512

In the transportation area, the barriers are perhaps even 461
 more onerous, with a motor vehicle system in place that 462
 has evolved for over a century to support gasoline-powered, 463
 internal combustion engine vehicles. In most places of the 464
 world, the vehicle-refueling infrastructure and vehicle ser- 465
 vice industries that support the use of motor vehicles are 466
 entrenched in a way that will make change away from the 467
 status quo inevitably difficult. Furthermore, due to envi- 468
 ronmental pressures and partly in response to progress in 469
 fuel cell development, other options for reducing fuel con- 470
 sumption and emissions from motor vehicles are also under 471
 intense development; they are a "moving target". Such 472
 options as hybrid-electric vehicles, with a small gasoline 473
 or diesel engine coupled with a battery-powered electric 474
 driveline, are capable of achieving impressive levels of effi- 475
 ciency and environmental performance at cost levels that 476
 FCVs will be challenged to meet. 477

Thus, a key aspect of the early commercialization of 478
 fuel cell systems is to find niches in which they have 479
 competitive advantages, and to exploit these niches in order 480
 to build production volume, lower costs, and ultimately 481
 reach other market niches, which in turn will lead to even 482
 greater production volumes and lower costs. This process 483
 has come to be known as the "virtuous cycle", and almost 484
 all successful technologies have benefited from it. A key 485
 aspect of the virtuous cycle is the cost reduction that occurs 486
 through a combination of scale economies in production, 487
 and also learning that takes place with regard to both 488
 product and manufacturing process design. 489

The concept of the "learning curve" or "experience 490
 curve" captures this phenomenon, whereby manufacturing 491
 cost histories of many different products have shown a con- 492
 sistent pattern of cost reduction with increases in cumulative 493
 production volume. In essence, manufactured products tend 494
 to decline in cost by 10–30% with each doubling of *cumulative* 495
 production volume (see^[12] for review of the literature 496
 and application to automotive fuel cell technology). This 497
 logarithmic effect means that cost reductions are achieved 498
 rapidly early in a product's history, when doublings in 499
 cumulative production occur relatively quickly, and then 500
 slow down as the doublings take longer to achieve. Thus, 501
 if a product can gain an initial foothold in the market due 502
 to some competitive advantage, this can trigger the virtuous 503
 cycle and ultimately allow a new technology to break into 504
 a market that is dominated by an incumbent technology. 505

Thus, it is imperative that fuel cell systems for station- 506
 ary and transportation applications find initial niches where 507
 they are attractive, even if these niches are relatively small. 508
 For stationary systems, this might include the market for 509
 "premium power" where certain uses require electricity reli- 510
 ability that is much greater than that of grid power. Onsite 511
 fuel cell systems should be able to generate power with 512

513 a high degree of reliability, particularly if combined with
 514 backup systems, and this provides the type of competitive
 515 advantage that could give them a foothold in the market
 516 from which they can expand. In the transportation sector,
 517 the desire to achieve zero tailpipe emissions for vehicles
 518 that operate in dense urban areas is a driver that could
 519 give FCVs an important niche. The only zero-emission
 520 vehicle type other than direct-hydrogen FCVs that is prac-
 521 tical at the present time is the battery EV, and this vehicle
 522 type is characterized by short driving ranges, long recharge
 523 times, and potentially high lifecycle costs. To the extent
 524 that zero-emission vehicles are encouraged or even man-
 525 dated in certain areas, direct-hydrogen FCVs may have to
 526 compete only with battery EVs and not the entire suite of
 527 vehicle technology options. This could give them a much
 528 firmer foothold to break into motor vehicle markets.

529

530

531 6 CURRENT STATIONARY SYSTEM 532 COMMERCIALIZATION PLANS

533

534 Demand for stationary fuel cell systems is expected to grow
 535 sharply over the next decade, and several companies are
 536 planning commercial products to enter this market. Allied
 537 Business Intelligence has forecast that 15 GW of fuel cell
 538 systems are expected to be in operation around the globe by
 539 2011, compared with just 75 MW in 2001.^[13] Meanwhile,
 540 the State of California has recently announced the formation
 541 of a stationary fuel cell collaborative program that seeks to
 542 install 20 MW of fuel cell systems in California by the end
 543 of 2002, with additional goals of having 100 MW of fuel
 544 cell generation by 2003 and 500 MW of fuel cell generation
 545 by 2004.^[14] This demand for fuel cell power fits into the
 546 overall context of the expected burgeoning growth of DG,
 547 which is expected to be a 20 GW year⁻¹ market on a global
 548 basis.^[15]

549 At present, the 200 kW PAFC units manufactured by IFC
 550 are the only commercially available stationary fuel cell sys-
 551 tems on the market. However, a host of other companies
 552 have plans for products for the stationary market. These
 553 include Ballard Generating Systems, Plug Power, IdaTech,
 554 and Avista Labs for PEMFCs in residential and commer-
 555 cial buildings; Nuvera Fuel Cells for PEMFCs in remote
 556 telecommunication and UPS applications; Siemens West-
 557 ingshouse, Honeywell, and Ceramic Fuel Cells for SOFCs in
 558 DG; and Fuel Cell Energy for larger-scale (300 kW–3 MW)
 559 MCFCs in DG. Meanwhile, other companies are focus-
 560 ing on somewhat more specialized niches, such as Proton
 561 Energy Systems and Hydrogenics, with PEMFC systems
 562 coupled to renewable hydrogen production via electrolysis;
 563 and H-Power with a focus on remote telecommunications
 564 (as well as niche transportation applications). While the

565 details of these companies' commercialization plans are
 566 largely proprietary, to the extent that they have been made
 567 public they tend to reveal an initial focus on regions with
 568 high electricity costs, market niches with needs for high
 569 reliability "premium power", areas where grid congestion
 570 is a problem, and areas where "opportunity fuel" such as
 571 landfill gas is available. The commercialization plans of
 572 these companies are thus for initial products that fit into
 573 niches where fuel cell power is particularly advantageous,
 574 presumably with the hope that broader markets will open
 575 up as manufacturing costs fall.

576 Several companies are focusing on PEMFCs for station-
 577 ary power generation, but the development of SOFC sys-
 578 tems has been given a recent boost by DOE. The Solid-State
 579 Energy Conversion Alliance (SECA) has recently awarded
 580 contracts totaling \$500 million to four different teams, in
 581 the hope of accelerating the development of SOFCs. These
 582 teams include those led by Honeywell, Siemens Westing-
 583 house, Delphi and Battelle, and Cummins Power Generation
 584 and McDermott Technology.^[16] DOE has a near term man-
 585 ufacturing cost goal of \$800 kW⁻¹ for SOFC stacks, with
 586 \$400 kW⁻¹ as a longer term goal.^[16]

587 588 589 590 7 CURRENT VEHICLE 591 COMMERCIALIZATION PLANS

592 FCVs are still in the research, development, and demon-
 593 stration phase, and all major automakers have substantial
 594 development programs underway. The FCVs closest to
 595 commercialization are buses. Fuel cell buses are now being
 596 demonstrated in Vancouver, Chicago, Sacramento, Palm
 597 Desert, and Washington, DC, and light-duty FCV test pro-
 598 grams are underway in Sacramento (under the California
 599 Fuel Cell Partnership), Germany, England and Japan. In
 600 a recent development, Ballard Power Systems and Xcell-
 601 sis, Inc. have announced that they will deliver 30 fuel cell
 602 powered "Zebuses" to European customers beginning in
 603 2002. These buses will employ the latest Ballard fuel cell
 604 technology, the Mark 902 system.^[17]

605 The exact commercialization plans for FCVs have not
 606 been disclosed by automakers, but they have suggested
 607 initial plans for introducing these vehicles. Table 1 lists the
 608 prototype vehicles that have been unveiled to date, along
 609 with the latest public statements by each company about
 610 their plans for commercialization. In general, introduction
 611 of FCVs into limited fleet applications is expected in
 612 the 2003–2005 timeframe – in the hundreds and perhaps
 613 thousands, with broader introduction to private consumers
 614 expected in about 2008–2010.

615 In general, automakers agree that hydrogen is the ulti-
 616 mate fuel for FCVs, and that FCVs in the future are

8 *Future prospects of fuel cell systems***Table 1.** Recent FCV prototypes and commercialization status for major automakers.^a

Manufacturers	Recent prototype vehicles	Fuel cell system	Commercialization timeframe

617 likely to operate directly on hydrogen. But there are
618 significant differences of opinion with regard to the evo-
619 lution of vehicles and refueling systems in the mean-
620 time. As of late 2001, General Motors, Toyota, Nissan,
621 Renault and Hyundai favor hydrocarbon-based FCVs, using
622 gasoline-like fuels, citing the fact that an infrastructure for
623 petroleum fuel distribution is already in place. Daimler-
624 Chrysler supports methanol fuel cells (along with other
625 options), believing that it is easier to convert methanol to
626 hydrogen than to convert gasoline, while using a similar
627

distribution system. Meanwhile, Ford and Honda are focus- 628
ing on direct-hydrogen FCV designs that avoid onboard 629
conversion from other fuel types, but require a hydrogen- 630
fueling infrastructure. 631

Another potential early application of fuel cells is APUs 632
for long-haul, heavy-duty trucks.^[18] In the US, these trucks 633
idle up to 10 h each day, and as much as 50% of total engine 634
run time. Idling consumes significant amounts of diesel 635
fuel, accelerates wear and tear on the engine, and generates 636
large amounts of noise, vibration and air pollution. The 637
638

639 total cost of idling heavy-duty trucks in the US is over a
 640 billion dollars per year for fuel and extra maintenance.^[19]
 641 An attractive APU that could replace the main engine is
 642 a diesel-fueled fuel cell. Two types of fuel cells could run
 643 on diesel fuel: proton-exchange membrane fuel cells of the
 644 type being developed for cars, with a device to convert the
 645 diesel fuel to hydrogen, or solid-oxide fuel cells that can
 646 operate directly on diesel fuel. Recreational vehicles, widely
 647 used in the US for overnight travel, are another potential
 648 fuel cell APU market; they spend a large amount of time in
 649 ecologically-sensitive national parks and other wilderness
 650 locations.

651 No companies have announced plans to commercialize
 652 fuel cell APUs, in trucks or any other vehicles, but BMW
 653 has made various announcements regarding the develop-
 654 ment of fuel cell APUs and applications in passenger
 655 cars.^[20] Freightliner and Cummins have participated in fuel
 656 cell APU development projects in heavy duty diesel trucks,
 657 but future plans have not been announced to date.

658 The use of fuel cells as APUs in long-haul trucks might
 659 lead to a migration of these clean, efficient devices to other
 660 trucks (and even cars), and also accelerate electrification
 661 of the truck's drivetrain, steering, braking and other acces-
 662 sories, leading to even further efficiency and environmental
 663 benefits. An analogy may be computers in cars, which ini-
 664 tially were used to control emissions, but soon gained much
 665 wider applications.

666 In addition to conventional cars, trucks, and buses, addi-
 667 tional transportation applications of fuel cell technology
 668 include scooters, "neighborhood" EVs and golf carts, fork-
 669 lifts, mining vehicles, airport baggage handling vehicles,
 670 airplanes, boats and even submarines. Commercialization
 671 plans for these vehicle types have not been made public in
 672 detail, but a few companies are clearly focusing on these
 673 markets. For example, Asia Pacific Fuel Cell Technologies
 674 hopes to work with a Taiwanese scooter developer to pro-
 675 duce fuel cell scooters for the Asian market, and several
 676 companies are experimenting with fuel cell powered golf
 677 carts and neighborhood EVs.

678 Fuel cell airplane designs have been developed by
 679 Aerovironment, which is testing the Helios high-altitude,
 680 unmanned, solar-powered aircraft. This plane soared to a
 681 record altitude of over 29 300 m (96 500 feet) (for a non-
 682 rocket powered aircraft) after being launched from Kauai,
 683 Hawaii in August 2001. The plane achieved a speed of
 684 275 km h^{-1} , or Mach 0.25, operating only on solar power.
 685 Battery systems have been used for initial tests of the
 686 Helios, but ultimately a fuel cell/electrolyzer system will
 687 be used, and the plane will then be able to fly for extended
 688 periods of time. Also, a small single-engine aircraft that
 689 is ultimately planned to operate with fuel cell power is
 690 being developed by Advanced Technology Products, Inc.

The first version of the aircraft will operate using lithium-
 ion batteries, but subsequent generations are planned that
 will use batteries augmented with a 12 kW PEMFC system,
 and subsequently with a 25–75 kW PEMFC.^[21]

With regard to marine applications, IFC has produced a
 30 kW PEMFC unit for the Navy's Lockheed Deep Quest
 vehicle. This submarine vehicle can operate at depths of
 up to 1500 m. Meanwhile, Ballard Power Systems has
 produced an 80 kW PEMFC fuel cell unit for submarine use
 that is methanol fueled.^[1] And, a German consortium led by
 STN ATLAS Elektronik GmbH, with four other companies
 and three research institutions, has developed the "DeepC"
 prototype fuel cell-powered, unmanned, underwater vehicle
 that is capable of traveling to depths of 4000 m. The
 consortium hopes to commercialize the vehicle in 2004 for
 oceanographic research and other undersea explorations.^[22]

8 SUMMARY AND CONCLUSIONS

Fuel cells have unique attributes that are attractive to
 automotive and electricity consumers, and also to automot-
 ive and electricity companies. These unique attributes are
 highly valued in certain market niches and segments. As
 costs come down and products enhanced, companies and
 governments will realign their policies and business strategi-
 es to accommodate fuel cell attributes and opportunities.

One can envision various scenarios and pathways by
 which fuel cells expand their presence. Shell International,
 well known for its sophisticated scenario planning, posits
 two energy scenarios for 2050.^[23] One of them is centered
 around and motivated by fuel cell advances. In this scenario,
 fuel cell sales start with stationary applications for busi-
 nesses willing to pay a premium for highly reliable power
 without voltage fluctuations or outages. They then spread
 to vehicles. By 2025, in this scenario, half of all vehicle
 sales in OECD countries and one quarter of all vehicle
 sales worldwide are fuel cell vehicles. Under this fuel cell
 "success story" scenario, fuel cells could eventually become
 the dominant energy conversion devices across all sectors,
 fueled by hydrogen in some settings and directly with nat-
 ural gas or landfill gas (with high temperature fuel cells) or
 methanol (with direct-methanol fuel cells) in others.

There are no obvious barriers to fuel cells' entry into
 the marketplace, and there are good reasons they will be
 attractive and prove to be a superior product. Their high
 efficiency, low emissions, ability to accommodate diverse
 fuels, high quality of generated electricity and their excep-
 tional suitability to hydrogen are strong factors in their
 favor. Three trends serve to reinforce the attractiveness
 of fuel cells: motor vehicles transitioning from mechan-
 ical and hydraulic systems to electrification, electricity

10 *Future prospects of fuel cell systems*

743 generating moving toward distributed generation, and con-
744 tinuing international commitments to reduce greenhouse
745 gas emissions and the environmental footprint of industrial
746 products.

747 However, despite great improvements in fuel cell power
748 density over the past decade, and demonstration of promis-
749 ing performance, both stationary and automotive fuel cell
750 systems face critical remaining challenges. These include
751 primarily cost reduction, where costs on the order of
752 \$500–800 kW⁻¹-peak are required for competitive station-
753 ary systems, and costs on the order of \$50–100 kW⁻¹-peak
754 are required for competitive FCVs. These cost levels are far
755 below current cost levels for various fuel cell technologies
756 that are in prototype and low-volume production. Addi-
757 tional challenges include fuel cell system durability, where
758 development goals are for 40 000 to 50 000 h between major
759 overhauls for stationary systems and 4000–5000 h for auto-
760 motive systems, development of efficient and low cost fuel
761 reformers, and development of hydrogen storage systems
762 for vehicles that are inexpensive, lightweight, compact, safe
763 and quick to refuel.

764 In the end, the future is highly uncertain. We remain
765 optimistic, particularly with regard to the use of fuel
766 cells in niche applications where they offer clear advan-
767 tages over other options. But when or whether fuel cells
768 flourish remains unknowable. It is entirely plausible, for
769 instance, that vehicles will follow a more incremental path
770 from today's internal combustion engine (ICE) systems to
771 hybrid electric cars that rely on small combustion engines
772 hybridized with electric-drive technologies. And it may
773 be that continuing refinements of these hybrid technolo-
774 gies will keep fuel cells at the margin, competitive only in
775 specialized niches. Stationary fuel cells for distributed gen-
776 eration may face greater than expected difficulties due to
777 durability problems or issues with integration into exist-
778 ing electrical grids. What is certain is that, at a mini-
779 mum, fuel cells will be an important technology alternative
780 that receives increasing attention and R&D resources for
781 some time.
